

Code:

```
import numpy as np  
a=np.array([123,1.36,'ABC'])  
  
print(a)  
  
print(a.dtype)
```

Screenshot:

- The U stands for Unicode.
- Unicode is a datatype in numpy that represents string.
- int for integer float for float and so for other datatypes.
- When an array is created and string is stored in it, it prints the maximum length that a string took to be stored.
- The <U32 here doesn't show the maximum length like 3. Instead it prints a default size that is set in the numpy for the array with mixed elements.
- Instead of calculating the maximum length an element took it prints a default size. If the string is greater than 32 it will automatically change its output to <U40.
- In <U21 it finds the longest string then reserves the space for every element as per the size of the longest string length. For example if the longest string is of 21 characters it reserves the space of 21 characters for all the other elements irrespective of their length.
- For mixed datatype of elements it shows a default fixed-size.
- Numpy shows the datatype as well as the size or space taken by the elements when they are stored.
